## 1 Basic definitions

**Definition 1.1. Support** The set of values a random variable can take (set of all the numerical realizations of outcomes) e.g. for a binary random variable X, it's support is  $R_X = \{0, 1\}$ 

**Definition 1.2. Sample Point** In an experiment, a sample point is one of the possible outcomes of experiment denoted by  $\omega$ 

**Definition 1.3. Independent Events** Two events A and B are independent if and only if

$$P(A \cap B) = P(A) * P(B) \tag{1}$$

**Definition 1.4. Jointly/Mutually Independent Events** Let  $E_1, ..., E_n$  be n events.

 $E_1,...,E_n$  are jointly independent(or mutually independent) if and only if for any sub-collection of k events  $(k \le n)E_{i1},...,E_{ik}$ :

$$P(\bigcap_{j=1}^{k} E_{ij}) = \prod_{j=1}^{k} P(E_{ij})$$
 (2)

**Definition 1.5. Random Variable** A random Variable X is a function from sample space  $\Omega$  to set of real numbers  $\mathbb{R}$ , i.e  $X : \Omega - > \mathbb{R}$ .

The real number  $X(\omega)$  associated with sample point  $\omega \in \Omega$  is called a realization of the random variable. The set of all possible realizations is called the support and denoted by  $R_X$ 

**Definition 1.6. Probability Mass Function** The PMF of a discrete random variable X is a function  $p_X : \mathbb{R}^- > [0, 1]$  such that

$$p_X = P(X = x) \quad \forall x \in \mathbb{R}$$
 (3)

where P(X = x) is the probability of realization of random variable X will be equal to x. Basically PMF is numerical realizations — > respective Probabilities.

Definition 1.7. Distribution Function/Cumulative Distribution Function If X is a random variable, its distribution/cdf is a function  $F_X : \mathbb{R}^- > [0, 1]$  such that

$$F_X(x) = P(X \le x) \quad \forall x \in \mathbb{R}$$
 (4)

**Definition 1.8. Expected Value of a Random Variable** The expected value of random variable X is the weighted average of the values that X can take on where each possible realization value is weighted by its respective probability i.e.

$$\mathbf{E}[X] = \sum_{x \in R_X} x p_X(x) \tag{5}$$

**Definition 1.9. Quantile** The p-Quantile of a Random Variable X is given  $p \in (0,1)$  and X having cumulative distribution function(cdf) to be  $F_X(x)$ , the p-Quantile is:

$$Q_X(p) = \min\{x \in R : F_X(x) \ge p\}$$
(6)

This translates roughtly equivalently to the definition of percentiles. e.g 0.5-quantile is a median. 0.25-Quantiles are quartiles etc.

**Definition 1.10. Deviation of a Random Variable** The Deviation of a Random Variable is its difference from its mean value/Expected value. It is denoted by

$$\overline{X} = X - \mathbf{E}[X] \tag{7}$$

Deviation of Random Variable is also a random variable in it's own respect.

**Definition 1.11. Variance** It is a measure of dispersion of a random variable. Let X be a random variable. The variance of X, denoted by Var[X] is defined as follows:

$$Var[X] = \mathbf{E}[(X - \mathbf{E}[X])^2] = \mathbf{E}[\overline{X}^2] = \mathbf{E}[X^2] - \mathbf{E}[X]^2$$
(8)

You can also think of it as mean of the square of the deviations of original random variable.

**Definition 1.12. Standard Deviation** It is a measure of dispersion of a random variable. Let X be a random variable. The standard deviation of X, denoted by stdev[X] or std[X] is defined as follows:

$$stdev[X] = \sqrt{Var[X]} \tag{9}$$

You can also think of it as rms deviation.

**Definition 1.13. Covariance** It is a measure of association between two random variables. Covariance of two random variables X and Y is , provided Expected values are well defined,

$$Cov[X, Y] = \mathbf{E}[(X - \mathbf{E}[X]) * (Y - \mathbf{E}[Y])] = \mathbf{E}[\overline{X} * \overline{Y}]$$
(10)

where we say deviation of X is  $\overline{X} = X - \mathbf{E}[X]$  and deviation of Y is  $\overline{Y} = Y - \mathbf{E}[Y]$ 

or in other words, covariance is expectation of product of deviations.

**Definition 1.14. Random Vector** It is a multidimensional generalisation of the concept of Random Variable. Associated probability functions have the word "joint" in front of them e.g. Joint PMF, Joint cdf etc correspond to a Random Vector.

## 2 Logistic

A logistic function or logistic curve is a common 'S' shaped curve with equation:

$$f(x) = \frac{L}{1 + e^{-k(x - x_0)}} \tag{11}$$

where

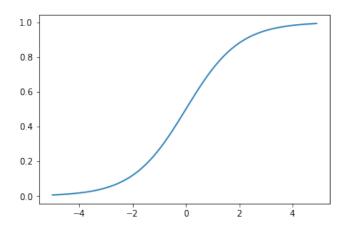

- $\bullet$  e = natural log
- $x_0 = x$ -value of sigmoid's midpoint
- $\bullet$  L = the curve's maximum value
- $\bullet$  k = the steepness of the curve

## 2.1 Standard Logistic

The standard logistic function is the logistic function with parameters given  $(k = 1, x_0 = 0, L = 1)$  i.e.

$$\sigma(x) = \frac{1}{1 + e^{-x}} \tag{12}$$

which when plotted looks like

Why is logistic function so important? Because it can take any real input  $x, (x \in R)$ , whereas the output always takes values between 0 and 1, and hence is interpretable as probability.
